

- GENERAL NOTES**
- Interpret per ISO 128. Tolerances ISO 2768-mK unless stated. Dimensions in mm.
 - Charging, evacuation and sealing per VC-300. NEVER charge before diffusion bonding — bond temperature exceeds the fluid critical pressure envelope.
 - CONFIG A requires forced air $\geq 1 \text{ m/s}$. For still air use CONFIG B (VC-202); a 1.5 mm fin pitch chokes natural convection to $h = 0.03 \text{ W/m}^2\text{K}$.
 - Orientation-independent: 10.5 kPa capillary head vs 0.66 kPa gravity head over 68 mm.

BILL OF MATERIALS — ASSEMBLY VC-100					
ITEM	QTY	PART No.	DESCRIPTION	MATERIAL	MASS
1	1	VC-101	CHAMBER BASE, POCKETED, 100 POSTS	Cu C10200 / C1020	77.4 g
2	1	VC-102	CHAMBER LID, 1.0 THK, FILL PORT	Cu C10200 / C1020	41.4 g
3	1	VC-103	SINTERED WICK — IN-SITU PROCESS	Cu POWDER 45-75um	9.6 g
4	1	VC-201	FIN STACK, 43 FIN — FORCED AIR	Al 1100-H14	88.1 g

NOTES

- MATL: OXYGEN-FREE copper C10200 / JIS C1020, annealed. Tough-pitch copper (C11000 / JIS C1100) is PROHIBITED: it embrittles in the 950 C hydrogen sinter.
- Posts integral with base — machine from solid or coin.
- Bond faces (rim + post tops): flatness 0.02, Ra 0.4 max.
- Grooves run ONE direction only, interrupted at posts.
- Post top faces coplanar with rim within 0.015.
- Deburr 0.1 max. No burrs into cavity.
- Vacuum degrease + acid pickle before sintering.

CRITICAL CHARACTERISTICS

FEATURE	NOMINAL	TOL	CRITICAL TO
Floor thickness	1.0	+0.05 / -0.00	evaporator R th
Post height = pocket depth	3.0	±0.015	lid bond / burst
Rim + post-top flatness	—	0.02	hermeticity
Groove depth	0.20	±0.03	capillary return
Bond face roughness	Ra 0.4	max	diffusion bond
Post position	true position	Ø0.10 MMC	lid land alignment

WICK ZONE SECTION

SCALE 10:1 — ASSEMBLED

Zones A, B and C are sintered in ONE cycle and must be capillary-continuous:
condensate returns C → B → A. A break at the B/A junction causes evaporator dry-out.

WICK ZONES			
ZONE	LOCATION	THK	FUNCTION
A	Pocket floor, around posts	0.40	evaporator + liquid supply
B	Pocket side walls (4 off)	0.30	perimeter return path
C	Lid underside, posts masked	0.20	condensate collection

SINTER PROCESS		
PARAMETER	VALUE	TOL / NOTE
Cu powder, spherical, gas-atomised	45 - 75 um	sieved, -200/+325 mesh
Effective pore radius	12.6 um	= 0.21 x d(particle)
Porosity	55 %	± 5 %, quantitative metallography
Permeability (Blake-Kozeny)	1.97e-11 m2	derived, not measured
Capillary head, water @ 60 C	10.5 kPa	vs 0.66 kPa gravity head
Sintering temperature	950 C	± 10 C
Dwell	30 min	at temperature
Atmosphere	H2 (dew pt < -40 C)	or vacuum < 1e-3 Pa
Ramp / cool	10 C/min / furnace cool	no quench
Tooling	graphite mandrel + mask	masks post tops, rim, fill port

WICK ACCEPTANCE		
ACCEPTANCE TEST	REQUIREMENT	METHOD
Porosity	55 % ± 5	image analysis, 3 sections
Wick thickness A	0.40 ± 0.05	cross-section, 5 points
Capillary rise, water	> 25 mm in 60 s	witness coupon, vertical
Groove continuity	open, no blockage	back-light / CT, first article

POWDER TRADE STUDY — WHY 45-75 um				
POWDER	r eff	dP cap	Q cap VERT	VERDICT
25 um	5.2 um	25.2 kPa	348 W	clogs, low K
45 - 75 um	12.6 um	10.5 kPa	804 W	SELECTED
100 um	21.0 um	6.3 kPa	1279 W	coarse, ok
150 um	31.5 um	4.2 kPa	1802 W	marginal tilt
400 um (original drawing)	100 um	0.4 kPa	0 W	FAILS — < gravity

The original 200 um pore spec gives 380 Pa of capillary head against a 500 Pa gravity head
over 68 mm: the wick cannot lift liquid at all in any vertical orientation.

CAPILLARY PRESSURE BUDGET — WORST CASE, VERTICAL		
TERM	VALUE	NOTE
Capillary head available 2σ/r	10 508 Pa	water @ 60 C, r = 12.6 um
Liquid loss through wick + grooves	– 12.6 Pa/W	at 804 W: 10 127 Pa
Vapour loss through 2.40 core	– 0.2 Pa/W	negligible
Gravity head, 68 mm adverse	– 656 Pa	vertical, evaporator up
Margin at 113 W design point	+ 8 428 Pa	7.4 x

The wick is sized by the vertical case. Horizontal operation carries 858 W and is never the limit.

PROCESS NOTES

- Mask post top faces and the 4.0 rim before sintering — sintered powder on a bond land destroys hermeticity.
- Mask the fill port bore. Powder in the pinch-off tube prevents a gas-tight cold weld.
- Grooves must remain open under the wick. Verify by back-light or CT on the first article.
- Sinter and diffusion bond may share one furnace cycle only if the bond fixture applies load after the sinter dwell; otherwise run separately.
- No organic binders. Any residue outgasses into the sealed chamber as non-condensable gas.

EXPERIMENTAL COUPON — NOT A PRODUCTION CONFIGURATION — SEE PHYSICS NOTE BELOW

Mesh: 10 um SUS 316L — NOT 50 um. Maxsorb III fines pass a 50 um mesh and foul the wick.

Carbon bake-out 250 C / 8 h / < 1e-3 Pa before installation, transferred under vacuum.

Reservoir 0.5 g Maxsorb III needs >= 1.8 cm3 at 0.28 g/cc bulk density — the original 1.50 cm3

housing could not physically hold the charge. This coupon uses 30 x 12 x 6 = 2.16 cm3.

ADSORPTION EQUILIBRIUM — DUBININ-ASTAKHOV, METHANOL / MAXSORB III						
T evap	T res	P/Psat	UPTAKE	HELD	WICK FILL	RESULT
60 C	40 C	1.00	1.31 g/g	0.66 g	15 %	DRY
60 C	60 C	1.00	1.31 g/g	0.66 g	15 %	DRY
60 C	100 C	0.24	1.06 g/g	0.53 g	35 %	DRY
60 C	127 C	0.11	0.77 g/g	0.39 g	58 %	marginal
60 C	169 C	0.03	0.42 g/g	0.21 g	90 %	wet

4

PHYSICS NOTE — WHY THE PASSIVE VERSION CANNOT WORK

- In a sealed pure-substance chamber the pressure is set by the evaporator: $P = P_{\text{sat}}(T_{\text{evap}})$. The carbon sees the relative pressure $P / P_{\text{sat}}(T_{\text{res}})$.
- A reservoir on the condenser side always satisfies $T_{\text{res}} \leq T_{\text{evap}}$, so $P/P_{\text{sat}} \geq 1$ and the carbon saturates: it takes 0.66 g of a 0.75 g charge and the wick runs at 15 % fill. That is permanent dry-out, not pressure control.
- Keeping the wick wet needs the reservoir ~110 K ABOVE the chip. A working vapour chamber is isothermal, so no passive layout can deliver that. It requires the heater and valve drawn above.
- Overcharging to 1.90 mL keeps the wick wet, but then liquid always remains, the pressure stays at P_{sat} , and the carbon buys nothing thermally. Its only genuine residual function is as a non-condensable gas getter — for which tens of mg suffices, not 0.5 g.

COUPON vs PRODUCTION VC-100		
	WITH CARBON	WITHOUT
Wick fill at equilibrium	15 %	125 %
Q at 2 m/s forced air	0 W (dry)	113 W
Transient buffer	722 J (heater needed)	0 J
Parts count / failure modes	+ valve, heater, control	baseline

INSTRUMENTATION		
MEASUREMENT	INSTRUMENT	PURPOSE
T1..T4	type-T TC, ± 0.2 K	gradient map
Chamber pressure	capacitance manometer	verify $P_{\text{sat}}(T)$
Reservoir mass	in-situ load cell ± 1 mg	uptake vs time
Heater power	4-wire, ± 0.5 %	energy balance
Valve state	open / closed	isolate the carbon

TEST MATRIX		
#	TEST	MEASURES
1	Valve CLOSED, sweep 0-150 W	baseline R th, no carbon
2	Valve OPEN, reservoir unheated	dry-out rate + time constant
3	Valve OPEN, reservoir held 110 K above die	whether the wick recovers
4	Valve OPEN, cyclic 10 W bursts, heater regen	usable buffer energy (722 J predicted)
5	1000 h hold, valve OPEN, unheated	NCG getter benefit vs dry-out cost

5

5

COUPON NOTES

- Fluid is METHANOL for this coupon (activated carbon is hydrophobic; water uptake is poor). Accept the 7.3x lower merit number — this coupon measures adsorption, not peak cooling.
- Methanol charge 1.90 mL so the wick stays wet with the carbon saturated. Do not run at 1.00 mL.
- The valve is what makes this an experiment rather than a defect. A production unit has no valve, so it has no way to stop the carbon draining the wick.

5

5

IF TEST 4 SUCCEEDS — PATH TO A PRODUCT

- Move the reservoir onto the die's own heat path, upstream of the chamber, so it is genuinely hotter than the evaporator without a valve.
- Replace the bellows valve with a thermally actuated one-way element, or accept a control loop driving the regeneration heater.
- Budget 722 J against ~5 g of added mass and a new hermetic joint. Compare against simply adding 15 K of copper (+50 g).
